(Received: January 9, 2014. Accepted: February 27, 2014)

ABSTRACT. Communities of hay meadows with *Arrhenatherum elatius* form phytocenoses of at least two plant communities: *Arrhenatheretum elatioris* – semi-natural habitats, and *Tanaceto-Arrhenatheretum elatioris* – ruderal habitats. The communities of tall oat-grass include approximately 150 species of vascular plants. In central Poland *Tanaceto-Arrhenatheretum* is the main habitat for many species characteristic of the *Arrhenatherion* alliance, including: *Pastinaca sativa*, *Knautia arvensis*, *Tragopogon pratensis*. Hay meadows are vulnerable (VU) components of vegetation of the characterized region. There is a need to verify syntaxonomic units within the *Arrhenatherion* alliance and phytosociological identifiers of Natura 2000 habitats – extensively used hay lowland meadows (6510).

KEY WORDS: *Arrhenatherion*, meadow, vegetation, Natura 2000, central Poland

INTRODUCTION

Communities of hay meadows (*Arrhenatherion*) are considered to be a fairly common component of Polish lowland landscape. The most common one is the community with the dominance of tall oat-grass (*Arrhenatheretum elatioris*) (MATUSZKIEWICZ 2008). Their prevalence in the country is evidenced by the frequent presence of this community in the lists of protected habitats in Natura 2000 areas. The widely understood *Arrhenatheretum elatioris* also stands out against other non-forest communities, with rather abundant literature on this topic: geographical distribution, habitat requirements, species abundance and diversity (see KUCHARSKI & MICHALSKA-HEJDUK 1994). The research on plant cover of meadows in central Poland made in the late twentieth century showed that one of the most vulnerable communities in these habitats is *Arrhenatheretum elatioris* (KUCHARSKI 1999). It is considered to be the endangered component of landscape vegetation in other Polish regions as well (CELIŃSKI et al. 1997, BRZEG & WOJTERSKA 2001, MŁYNKOWIAK & KUTYNA 2011).

This paper presents the current state of *Arrhenatherum elatius* communities in central Poland.

The main objectives of the paper are:

- determination of the diversity of communities of *Arrhenatherum elatius* occurring in central Poland,

- comparison of oat-grass communities in rural areas with the tall oat-grass communities in urban areas,
- presenting the degree of threat of tall oat-grass communities in central Poland.

CHARACTERISTICS
OF THE STUDY AREA

Central Poland is considered to be the central part of the country, which includes the area of the Łódź region and the neighboring municipality regions, adjacent to the boundaries. This area coincides with the Central Poland area, as described by Mowszowicz (1978). This geomorphologically diverse area lies on the border between the provinces of Central European Lowland and Polish Highlands. It consists of Silesian-Cracow Highland and Małopolska Highland, where Mesozoic and Paleozoic rocks come onto the surface, and even of Central Poland Plain and South Baltic Lake District, composed of Quaternary sediments (KONDRACKI 2002). In the geobotanical division of the country by SZAFER (1977), this area has a transitional, lowland-highland nature. The southern part lies in the northern part of the Central Highlands Belt and the northern part in the Belt of the Great Valleys.

The area is characterised by a lowering of the surface to more than 300 m above sea level in the south to 80 m above sea level in the north (TURKOWSKA 2001). The feature of this area is also a shortage of water, which is a consequence of, among others: the position in the watershed of the Vistula and Oder rivers and significant deforestation area (lowest forest cover in Poland) (MAKSYMUK 2001). The climate of the area is characterized by a relatively small spatial diversity. The largest differences were noted in precipitation, ranging from 500 mm in the north of the region, to more than 600 mm in the upland part (KŁYSIK 2001).

MATERIALS AND METHODS

The study covers the results of field studies carried out in the grassy central Poland plant communities in 2000–2013. It presents preliminary data on diversity of communities of *Arrhenatherum elatius* and their distribution, trends in vegetation and the degree of threat. The object of the study was plant cover of hay meadows used in agriculture, lawns in urban areas (mown no more often than twice a year) and roadsides (mown at least once a year). In uniform vegetation patches over 50 phytosociological relevés were taken by Braun-Blanquet method, 48 of which are presented in Table 1 (PAWŁOWSKI 1977). Phytosociological relevés on roadsides were taken in strips of vegetation not narrower than 4 m.

For distinguished plant communities, values of forming them plant systematic species communities were calculated (PAWŁOWSKI 1977). Syntaxonomy of

recorded species is presented according to MATUSZKIEWICZ (2008). Nomenclature of vascular plants is consistent with MIREK et al. (2002). Distribution of *Arrhenatherum elatius* meadows in central Poland is shown in cartogram (Fig. 1). A large-scale ATPOL cartogram of the side of a square 10 km was used (ZAJĄC 1978). Due to the small share of bryophytes in plant cover patches these plants were omitted in further analyses.

RESULTS

Current results of studies of the plant cover of meadows in central Poland indicate that grass monocultures are the dominant component of the plant cover on economically used grasslands. Hay grassland habitats are affected to a greater extent than wet ones. This process is accompanied by withdrawal of some of the species associated with the extensively used hay meadows from these habitats. They participate in the formation of new plant communities built by species characteristic of the *Arrhenatherion* alliance in ruderal habitats (including urban lawns and roadsides).

Arrhenatherum elatius is one of the most important grasses occurring on grasslands. It is a species characteristic for the *Arrhenatheretum elatioris* which is the most typical form of *Arrhenatherion* alliances. This species is also listed in grassland communities developing in ruderal areas. Phytocenoses of communities with tall oat-grass studied in 2000–2013 were built by about 150 species of vascular plants, representing over 30% of taxa recorded in the meadows of central Poland (KUCHARSKI 1999). In phytocenoses of *Arrhenatherum elatioris* occurring on agricultural land, 137 species of vascular plants were found. Patches of *Tanaceto vulgaris-Arrhenatheretum elatioris* were created by 77 species of vascular plants.

Initial results have shown that in central Poland, tall oat-grass and species characteristic for *Arrhenatherion elatioris* alliance create at least two plant communities: *Arrhenatheretum elatioris* and *Tanaceto vulgaris-Arrhenatheretum elatioris*.

Here is their syntaxonomy and diversity:

Table 1. cont.

Arrhenatheretum elatioris was reported on extensively used meadows, both on the terraces of river valleys lagoon territories and beyond. Seven syntaxonomic units of the rank of sub-association were found (Table 1). The most frequently reported was *Arrhenatheretum elatioris typicum*. It is characterised by a very diverse floristic composition; in addition to tall oat-grass and yarrow, species characteristic for *Molinio-Arrhenatheretea* appear with great frequency. It is usually recorded in river valleys, rarely beyond. One of the more interesting syntaxa is *Arrhenatheretum elatioris alchemilletosum*, which usually is described in the southern regions of the country (see KUCHARSKI & MICHALSKA-HEJDUK 1994). In the described area it was found in the south, usually outside the river valleys or on small upland fields in the valleys of large rivers. The community is extensively grazed. *Arrhenatheretum elatioris brizetosum mediae* is the most "natural" community of the above syntaxa. It was noticed on the most neglected meadows, rarely mown and fertilized, and growing on acidic and not very fertile soil. On more fertile and moist habitats of variable humidity, phytocenoses of *A. e. sanguisorbetosum officinalis* are recorded. Phytocenoses with a large share of common hogweed (*A. e. heracleotosum*) develop on mineral-organic surface. These are meadows fertilized and mown twice a year. In the valleys of large rivers (the Warta, Pilica, Bzura) of a relatively fertile ground, patches *A. e. alopecuro-polygonetosum bistortae* communities are reported. The most common syntaxonomic unit on hay meadows is *A. e. dactyletosum*. Phytocenoses develop on damp habitats within intensively used meadow complexes.

Phytocenoses of *Arrhenatherum elatius* with significant participation of species of *Artemisieta vulgaris* and *Agropyretea intermedio-repentis* were described, among others, on the area of Giessen (Hesse) as ruderal meadows ("Ruderale Wiesen") – *Tanaceto vulgaris-Arrhenatheretum elatioris* (FISCHER et al. 1985). Similar community on the area of Berlin has been described as *Dauco-Arrhenatheretum elatioris* (KOWARIK & LANGER 1994) and on roadsides in the western part of Germany (ULLMANN et al. 1990). *Tanaceto-Arrhenatheretum* also reported on the area of Austria (MÜLLER 1995, ESSL 2005) and Bulgaria (VELEV et al. 2011). Diagnostic species of the communities are: *Artemisia vulgaris*, *Cirsium arvense*, *Convolvulus arvensis* and *Dactylis glomerata*. Permanent components of this syntaxon include: *Achillea millefolium*, *Arrhenatherum elatius*, *Elymus repens* and *Taraxacum officinale* (VELEV et al. 2011). In the region of Lodz, ruderal habitats (lawns, roadsides) are home to relatively floristically rich communities in which tall oat-grass is accompanied by: *Pastinaca sativa*, *Daucus carota*, *Cirsium arvense*, *Heracleum sphondylium*, *Knautia arvensis* and species of *Artemisieta* class, as well as and thermophilic grasslands. They were described as *Tanaceto vulgaris-Arrhenatheretum*. So far, that community has not been described on the Polish

<i>Molinio-Arrhenatheretea</i>	65.10	36.63
<i>Festuco-Brometea</i>	1.61	1.26
<i>Koelerio-Corynephoretea</i>		
<i>Artemisieta vulgaris</i>	1.43	19.89
<i>Agropyretea intermedio-repentis</i>	4.06	15.47
Others	7.64	9.11

Explanations: 1 – *Arrhenatheretum elatioris*, 2 – *Tanaceto vulgaris-Arrhenatheretum elatioris*.

territory. Patches of the community have a significant share of species characteristic for hay meadows and ruderal habitats (*Artemisieta* and *Agropyretea intermedio-repentis*) and a small proportion of species characteristic for other types of meadows (*Molinio-Arrhenatheretea*; Table 2). They are also characterised by higher species richness. On the phytosociological relevés taken on the *Tanaceto-Arrhenatheretum* patch, 23 species of vascular plants were reported on average, while in case of *Arrhenatheretum elatioris* their number is slightly above 20 species.

DISCUSSION

Arrhenatherum elatius is short-term grass of high development dynamics but largely dependent on management. This grass does not tolerate very low mowing, grazing and trampling. Cessation of use (mowing) causes replacement of it by nitrophilous perennials. After cessation of fertilization on very fertile habitats, it is displaced by species of psammophilous grasslands (SZERAFIMOWICZ 1960, JANKOWSKA 1967, HENN et al. 1988, KORNAŚ & DUBIEL 1990, FALKOWSKI et al. 1994).

In most works devoted to meadows published in the twentieth century, communities with tall oat-grass were treated as collective communities of *Arrhenatheretum elatioris* (previously *Arrhenatheretum medieeuropaeum*). Numerical methods for the analysis of phytosociological records caused the division of the syntaxon into a couple of smaller plant communities. These include: *Pastinaco sativae-Arrhenatheretum elatioris* Passarge 1964 (considered as a synonym for *Arrhenatheretum elatioris*), *Ranunculo bulbosi-Arrhenatheretum elatioris* Ellmauer in Mucina et al. 1993, *Ranunculo repensis-Alopecuretum pratensis* (Eggler 1933) Ellmauer in Mucina et al. 1993, *Tanaceto vulgaris-Arrhenatheretum elatioris* Fischer ex Ellmauer in Mucina et al. 1993, *Lilio bulbiferi-Arrhenatheretum elatioris* Ružičková 2002 (ŠKODOVÁ & JANÍŠOVÁ 2008, JANÍŠOVÁ et al. 2010, OPERA & SÍRBU 2010, VELEV et al. 2011, LENGYEL et al. 2012). In Poland, the community is still described as *Arrhenatheretum elatioris* (KRYSZAK 2001,

BATOR 2005, KOZŁOWSKA 2005, KRYSZAK et al. 2008). The above-mentioned facts point to the need of verification of the currently used classification of hay meadows plant cover (*Arrhenatherion*) in Poland.

Oat-grass meadows (habitat 6510) have been considered a fairly common component of the landscape in central Poland. It is proven by the fact that they are frequently mentioned in Standard Data Forms as non-forest plant cover habitat in Natura 2000 areas. In the 90s of the 20th century, they covered the area of 11,230 ha (Table 3). The verification of data for Protection Tasks Plans for chosen objects indicates that the surface has been significantly reduced since the 90s of the 20th century. In the Pradolina Bzury-Neru, the 6510 habitat currently occupies less than 10% of the area recorded in the nineties of the previous century. Studies in other areas of the Natura 2000 sites in central Poland confirmed the above-mentioned phenomenon (KUCHARSKI 2013). Currently extensively used *Arrhenatherion elatioris* hay meadows are considered vulnerable (V) in the Łódź region (KUCHARSKI 2012, KUCHARSKI et al. 2012). The situation has been affected by the changes in grassland management, including, among others: intensification or abandonment of use, change of grassland to cropland, and the mechanization of hay harvesting. They caused that the surface of the primary alliance *Arrhenatherion – Arrhenatheretum elatioris* – has dramatically decreased. Existing phytocenoses of this community are characterized by low species richness. In semi-natural hay meadows in central Poland the species considered to be characteristic of these habitats have been withdrawing. They include as follows: *Pastinaca sativa*, *Knautia arvensis*, *Tragopogon pratensis*, and *Geranium pratense*. It is noted that some of them enter substitute habitats, which include ruderal meadows (Table 1).

Table 3. Participation of extensively used lowland hay meadows (6510) in the area of Natura 2000 sites in central Poland (based on Standard Data Form)

No.	Name of SAC	Area of SAC (ha)	% of cover habitat	Surface of habitat (ha)
1	Pradolina Bzury-Neru	21,886	17.00	3,721

12	Dolina Górnej Pilicy	11,193	17.70	1,981
13	Dolina Środkowej Warty	60,140	1.00	601

SUMMARY AND CONCLUSIONS

Oat-grass meadows in central Poland are the habitat for about 150 species of vascular plants, representing over 30% of taxa recorded in central Poland meadows.

In central Poland there are at least two communities, in which *Arrhenatherum elatius* makes a significant part in the patches. They are: *Arrhenatheretum elatioris* and *Tanaceto vulgaris-Arrhenatheretum elatioris*.

There is an urgent need to revise the currently used classification of communities in Poland within the *Arrhenatherion elatioris* alliance and adapting it to the system used in Central Europe.

Action should be taken to protect extensively used hay meadows, especially in the habitat areas of Natura 2000.

It is advisable to develop new phytosociological identifiers in order to assess 6510 habitat – extensively used lowland hay meadows (*Arrhenatherion*).
